Lecture 4:
A Transformational View of Cartography

**A Transformational View of Cartography**

W. R. Tobler

**ABSTRACT.** Cartographic transformations are applied to locative geographic data and to substantive geographic data. Conversion between locative aliases are between points, lines, and areas. Substantive transformations occur in map interpolation, filtering, and generalization, and in map reading. The theoretical importance of the inverses is in the study of error propagation effects.

Leonard Bernstein, in a recent television lecture, made an exciting, and largely successful, attempt to describe musical concepts in terms of Noam Chomsky's ideas concerning transformational grammars, as originally devised for linguistics. A similar, though less ambitious, attempt is made here to look at a range of cartographic activities from a transformational point of view. The treatment is not particularly Chomskian, although some work on picture languages is available.

generalizing lines on maps. As can be seen in his paper the method embodies a notion of spatial resolution. Since that time considerable further work has been done on line generalization, and it is now known that the problem admits of more solutions than were recognized in Perkal's early paper.

At the time Perkal wrote, computer cartography had not reached the large scale implementation which it now enjoys. Automatic plotters were not commonplace and he did not have avail-
A simplified view

Map input

Transformation

Map output
“...the entire process of making, and using a map can be viewed as a sequence of transformations”.

Types of Cartographic Transformation

- Geometrical Transformations: to "manipulate the locative aspects of the geographical data"
  - Map Projections
- Substantive Transformations: to "modify the substantive geographical data"
  - Map Generalization
  - Classification
Examples of a Cartographic Transformation

- Input data: World outline in Geographic Coordinates
- Software:
  - Ingests data
  - Establishes earth model (datum)
  - Establishes transformation (Projection)
  - Executes transformation
  - Saves transformed data
  - Displays transformed data
Cartographic Transformations

- The basis of Computer Cartography
- The core of Analytical Cartography
- Forms of Cartographic Transformation
  - Geometry

  - Symbolization
  - Scale
  - Data Structure and Data Model
  - Map Type
Map Geometry

- Point, Line, Area, (Volume) and Text
- Properties, position, length, area, shape, content
Map Attributes

2010 Census Results - United States
Total Population

Number of People by County or County Equivalent
- 2,000,000 to 9,818,665
- 1,000,000 to 1,999,999
- 500,000 to 999,999
- 250,000 to 499,999
- 100,000 to 249,999
- 50,000 to 99,999
- 10,000 to 49,999
- 0 to 9,999

Total U.S. Population: 308,745,538

Data Structure and Model

- Raster, vector, object
Map Type
A simplified view

Transformation

Map input

Map output

Inverse Transformation
Invertibility

…whether or not a Cartographic Transformation can be undone or reversed to produce the initial starting conditions – Clarke, 1995

Stable Transformation
- invertible
- “controllable and therefore are effectively programmed and modeled, especially with respect to the error introduced”

Unstable Transformation
- NOT invertible
- “the inverse transformation produces chaos”
For example: Map generalization

- Detailed map to coarse: throw away points and detail
- Coarse map to detailed: not possible without new data
**T1a: Earth to earth model**

For the WGS84

\[ a = 6,378,137 \]
\[ b = 6,356,752.3, \text{ so } f = 1/298.257 \]

*Figure 2.3* The ellipsoid. The long axis is the major axis, the short the minor axis. Half of each of these lengths is used to calculate the flattening of the ellipsoid.
T1b: Ellipsoid to symbolized globe
T2: Globe to map projection

- A transformation of the spherical or ellipsoidal earth onto a flat map is called a map projection.

- The map projection can be onto a flat surface or a surface that can be made flat by cutting, such as a cylinder or a cone.
Our simplified view

Map input

Transformation

Map output

Inverse Transformation
For example

- Maps1: Mercator projection
- Map 2: Mollweide
- Could go directly from Mollweide to Mercator
- Better to go back to Geographic coordinates (inverse) then forward to Mercator
- Possible infinite set of pairwise map conversions!
Forward and Inverse Projection Techniques

\[ X, Y = f(\varphi, \lambda) \quad \text{Forward equation} \]

\[ \varphi, \lambda = f(X, Y) \quad \text{Inverse equation} \]

- **Mercator projection (spherical assumption):**

  \begin{align*}
  \text{Forward equations:} & \quad X &= R \times (\lambda - \lambda_0) \\
  & \quad Y &= R \times \ln(\tan(\pi/4 + \varphi/2))
  \end{align*}

  \begin{align*}
  \text{Inverse equations:} & \quad \varphi &= \pi/2 - 2 \times \text{arctan}(e^{-Y/R}) \\
  & \quad \lambda &= x/R + \lambda_0
  \end{align*}
Map Projection Transformations

- Map projections represent many different types of transformation
- Perfectly invertible (one-to-one)
- One-to-many
- Many-to-one
- Undefined (non-invertible)
- Imperfectly invertible, e.g. on ellipsoid and geoid, computational error, rounding etc.
- Some transformations use iterative methods i.e. algorithms, not formulas
Matrices: Review

\[
\begin{bmatrix}
1 & 0 \\
0 & 1
\end{bmatrix}
\]

Has n rows
Has m columns
Has values
Has a leading diagonal

\[
\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix}\begin{bmatrix}
1 & 2 \\
3 & 4
\end{bmatrix} = \begin{bmatrix}
1 \times 1 + 2 \times 3 & 1 \times 2 + 2 \times 4 \\
3 \times 1 + 4 \times 3 & 3 \times 2 + 4 \times 4
\end{bmatrix}
\]

\[
= \begin{bmatrix}
7 & 10 \\
15 & 22
\end{bmatrix}
\]

Identity matrix

Matrix multiplication

Matrix inversion (T\(^{-1}\))

Powers, squares, etc
Maps as matrices

• \[
\begin{bmatrix}
x_1 & y_1 \\
x_2 & y_2
\end{bmatrix}
\] can have an \( n \times 2 \) matrix with as many coordinates as rows as we want
• Can also have \( x, y, \) and \( z \) as an \( n \times 3 \) matrix
• Transformation matrix only needs to be \( 2 \times 2 \)
• Or \( 3 \times 3 \) if \((x, y, z)\)
World Outline
(or any set of points, lines or areas)

- Consists of many sets of coordinate pairs \((x, y)\)
- Can be represented as a list or set \(X\), where \(X\) is a \(2 \times n\) matrix of points
- Matrix multiplication: Possible when one dimension is equal in sequence
- E.g. \(2 \times 2\) times a \(2 \times 10\)
- The transformation can be represented also as a matrix multiplication, with transformation \(T\)
- Works across sequences of transformations
Generic map as a matrix

- \([x_1, y_1, z_1]\]
- \([x_2, y_2, z_2]\]
- ..... 
- \([x_n, y_n, z_n]\]
- = \(X\)

\(n\) nodes, \(n-1\) segments
Sequences

- Data matrix $X$ (n x 2)
- Transformation matrix $T_1$ (2 x 2)
- Transformation matrix $T_2$ (2 x 2)
- Multiply $T_1$ by $T_2$ gives a new 2 x 2 matrix that performs BOTH transformations!
- Can repeat as often as we want
- Examples: Scaling, rotations, changes of origin, projections, etc.
- Original matrix $X$, transformation $T$, result $X'$
For example, in Inkscape
Rotate 60 deg CCW, then scale to 50%
Map Transformation Algebra

- Matrices have inverses, which reverse effect of multiplication to yield the identity matrix.

- Error creeps in when inversion does not result in identity matrix.

\[
X = \begin{bmatrix}
x_1 & y_1 \\
x_2 & y_2 \\
x_n & y_n \\
\end{bmatrix}
\]

\[
XT = X'
\]

Normal transformation.

\[
X'T^{-1} = X + E
\]

Inverse transformation.

\[
TT^{-1} = E \quad TT^{-1} = I
\]

Transformation both with and without error.
Equatorial Mercator Transformation

\[ x' = Rs(\lambda - \lambda_0) \]

\[ y' = Rs \log(\tan[\frac{\pi}{4} + \frac{\phi}{2}]) \]

\[ \begin{bmatrix} x \\ y \end{bmatrix} = T \begin{bmatrix} \lambda \\ \phi \end{bmatrix} \]

\[ \begin{bmatrix} \lambda \\ \phi \end{bmatrix} = T^{-1} \begin{bmatrix} x \\ y \end{bmatrix} \]
Planar Geometry vs. Spherical Geometry

- **Rule of Sines – Distance between points**

\[
\frac{\sin A}{a} = \frac{\sin B}{b} = \frac{\sin C}{c}
\]

\[
\frac{\sin p}{\sin P} = \frac{\sin q}{\sin Q} = \frac{\sin r}{\sin R}
\]

\[
radians = \frac{\pi}{180} \times \left(\text{degrees} + \frac{\text{minutes}}{60} + \frac{\text{seconds}}{60 \times 60}\right)
\]
Making projections

- Writing code modules
- Needs point data input
- Rasters create error, often autocorrelated
- Output must be stable
- Problems when crossing hemispheres
- Numerical handling
- Problem of repetition
- Store data in latitude and longitude, project on the fly?
- Tools for projections: Open source, code libraries, toolkits, web sites
Map projection software

- General Cartographic Transformation Package
- C-language (K&R style) version of GCTP
- PROJ.4 (Most popular)
- GEOTRANS (NGA)
- National Geodetic Survey (NOAA/NGS)
- GMT-3 The Generic Mapping Tools
- GeoConverter
- JMPL (Java Map Projections Library)
- PyProj (Python)
- GDAL

- Commercial
  - GeoCart
  - The Geographic Calculator
Some issues and research problems

- Display of pixel loss and replication in reprojecting raster data from the sinusoidal projection
  Denis White
Real Maps and Virtual Maps

- Joel Morrison (1974) called for an expanded definition of map in the computing era.

- Two crucial characteristics:
  - Whether a map is directly viewable as a cartographic image.
  - Whether it has a permanent tangible reality.
## Classes of Real & Virtual Maps

Moellering, 1984, Real Maps, Virtual Maps and Interactive Cartography
Transformations between Real & Virtual Maps

- Real $\Rightarrow$ Real – conventional cartographic processing;
- Real $\Rightarrow$ Virtual 3 – digitizing spatial data and storing them in a digital database;
- Virtual 1 $\Rightarrow$ Real – making hard copy image of a CRT screen image;
- Virtual 3 $\Rightarrow$ Real – digital cartographic plotting/drawing from a spatial database;
- Virtual 3 $\Rightarrow$ Virtual 1 – CRT display of digital spatial data from hard disk to CRT;
- Virtual 1 $\Rightarrow$ Virtual 3 – CRT screen editing spatial data stored on hard disk;
- Virtual 2 $\Rightarrow$ Virtual 3 – reading digital data from CD-ROM and storing them on hard disk;
- Virtual 3 $\Rightarrow$ Virtual 3 – mathematical transformation of digital spatial data resident on computer magnetic media. These transformations are sometimes called Tobler’s transformations.
